**ABSTRACT**

Hermaphroditism characterized by the presence of oocytes in the testes is described in the blue tilapia, *Oreochromis aureus*, for the first time. Testis-ova were observed in three of 24 spawning males exhibiting otherwise normal male morphology. The testis-ova appeared non-vitellogenic and lacked a follicle cell layer. It is speculated that the testis-ova did not become vitellogenic due to their association with Sertoli cells and the hormonal environment of the male.

**INTRODUCTION**

Intersexuality characterized by oocytes in the testis has been well documented among teleost fishes (Atz 1964, Reinboth 1970, Borg and van der Hurk 1983, Grout 1983). Testis-ova are often found in individuals which exhibit marked intersexuality with gonads divided into distinct ovarian and testicular regions or possessing intermediate secondary sex characters. However, oocytes in otherwise normal males have been reported (Reinboth 1962, Lillelund 1965). In a study of hermaphroditism among "Mbuna" cichlids, Peters (1975) suggested that oocytes in a testis was not conclusive evidence for its being a secondary testis. Furthermore, several specimens examined in that study possessed testis-ova yet exhibited male behavior. During a chromosomal analysis of testicular preparations from the blue tilapia, *Oreochromis aureus*, we observed oocytes in testes of three spawning males. This report offers further evidence for the widespread occurrence of testis-ova among cichlids. To our knowledge, this is the first report of hermaphroditism in *O. aureus*.

MATERIALS AND METHODS

Twenty-four male blue tilapia were collected by cast netting in irrigation canals of the Hillsborough River (Hillsborough County, Florida) during March 1984. Each specimen received an intraperitoneal injection of 0.1 percent colchicine (Sigma) at a dose of 0.1 ml per 10 grams body weight 6 hours prior to death to accumulate mitotic cells for the chromosomal analysis. Dissected testes were fixed in Bouin's solution, dehydrated through absolute ethanol, and embedded in glycol methacrylate (Polysciences) (Cole and Sykes 1974). For light microscopy, transverse sections 4 microns thick were stained with toluidine blue.

RESULTS AND DISCUSSION

All specimens examined were sexually mature and in breeding condition based on coloration and gonad size. Females possessed mature eggs within the ovary. Some were orally incubating eggs or fry.

Histologic examination of the testes revealed active spermatogenesis in all males with numerous meiotic and mitotic figures. In 3 of the 24 males, oocytes occurred among testicular tubules alongside normal spermatogenic tissue (Figure 1). The oocytes (25 to 75 microns in diameter) were nonvitellogenic and often degenerate. In a few, small nucleoli were associated with the nuclear membrane, characteristic of oocytes in the first meiotic prophase (perinucleolar state). Most of the testis-oocytes, however, possessed a single large nucleolus. A distinct follicle cell layer encompassing the testis-oocytes was not present. Sertoli cell processes retained these oocytes within the spermatogenically active tissue of the testis and apparently prevented them from becoming free within the tubule lumen. We speculate that the oocytes did not become vitellogenic because Sertoli cells cannot function as follicle cells, particularly in the presence of male hormones. The Sertoli cells may also be phagocytosing follicular cells.

Differentiation of oocytes in testicular tissues remains enigmatic. This phenomenon, however, poses basic questions as to mechanisms of germ cell differentiation and illustrates the variable nature of the teleost gonad.

ACKNOWLEDGMENT

The authors thank Mr. John Sproukin for cast netting the blue tilapia.
